

MYTH OR FACT

"Aluminum windows are *cold.*"

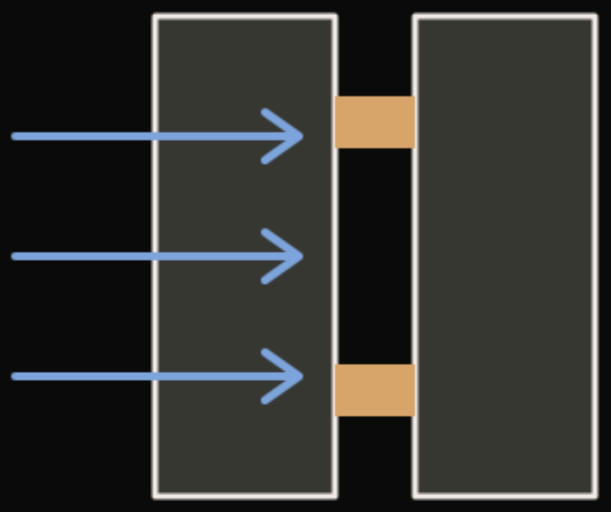

Then

One solid piece of metal.

Aluminum carries heat hundreds of times faster than the polyamide used to break it. A solid frame let the cold straight into the room.

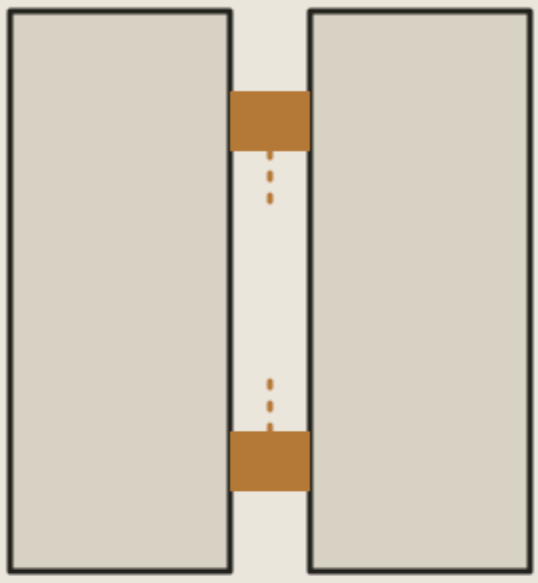

Now

A thermal break.

Today the frame is two profiles, an outer shell and an inner shell, with no solid metal path between them.

How

POLYAMIDE STRIPS

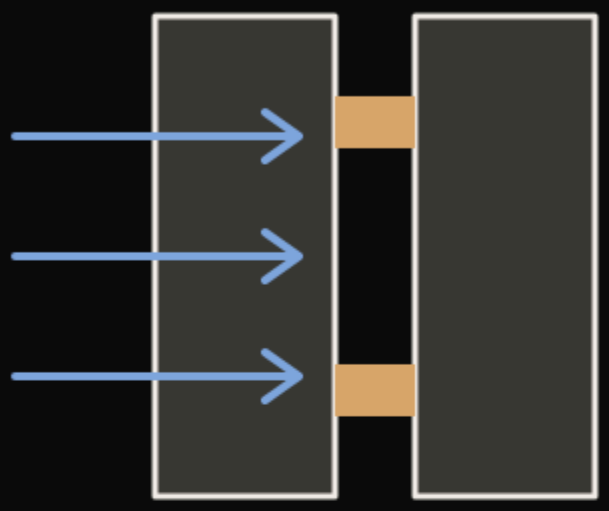

Joined by polyamide strips.

Glass-fibre reinforced polyamide strips are rolled in and the metal is crimped tight. Two frames, held together by something that refuses to carry heat.

0.14

U-factor of Reynaers MasterLine 10 with triple glazing.

Whole window, frame and glass together. Lower is better.

Fact: modern aluminum windows are slim and warm.
